Class plan

Yesterday: The canonical HANK model & fiscal policy

This morning: Closed economy monetary policy

Class plan

Yesterday: The canonical HANK model & fiscal policy

This morning: Closed economy monetary policy

For simplicity, we maintain our focus on real interest rate rules

Roadmap

- Review of monetary policy in the standard NK model
- Monetary policy in the canonical HANK model
- 3 Direct and indirect effects of monetary policy
- Cyclical income risk
- 5 Takeaway

Review of monetary policy in the

standard NK model

The NK model

- Recall the standard 3-equation NK model
 - separable preferences, sticky prices or wages, perfect foresight

$$c_t = c_{t+1} - \sigma^{-1} (i_t - \pi_{t+1})$$
 (EE)
 $\pi_t = \kappa c_t + \beta \pi_{t+1}$ (NKPC)
 $i_t = \pi_{t+1} + \epsilon_t$ (r-rule)

• Taylor rule instead of (r-rule): $i_t = \phi \pi_t + \epsilon_t$ (usually $\phi > 1$)

Monetary propagation in the NK model

$$c_t = c_{t+1} - \sigma^{-1} (i_t - \pi_{t+1})$$
 (EE)
 $\pi_t = \kappa c_t + \beta \pi_{t+1}$ (NKPC)
 $i_t = \pi_{t+1} + \epsilon_t$ (r-rule)

What does a **monetary policy shock** do, e.g. $\epsilon_t \downarrow$?

Monetary propagation in the NK model

$$c_t = c_{t+1} - \sigma^{-1} (i_t - \pi_{t+1})$$
 (EE)
 $\pi_t = \kappa c_t + \beta \pi_{t+1}$ (NKPC)
 $i_t = \pi_{t+1} + \epsilon_t$ (r-rule)

What does a **monetary policy shock** do, e.g. $\epsilon_t \downarrow$?

- 1. expansion in c_t so output $y_t \uparrow$, inflation $\pi_t \uparrow$
- 2. far out shocks to ϵ_t with large t are not dampened (Del Negro et al. 2023's "forward guidance puzzle")

Monetary propagation in the NK model

$$c_t = c_{t+1} - \sigma^{-1} (i_t - \pi_{t+1})$$
 (EE)
 $\pi_t = \kappa c_t + \beta \pi_{t+1}$ (NKPC)
 $i_t = \pi_{t+1} + \epsilon_t$ (r-rule)

What does a **monetary policy shock** do, e.g. $\epsilon_t \downarrow$?

- 1. expansion in c_t so output $y_t \uparrow$, inflation $\pi_t \uparrow$
- 2. far out shocks to ϵ_t with large t are not dampened (Del Negro et al. 2023's "forward guidance puzzle")

Two big questions re . . .

- transmission into consumption: 100% via Euler equation (implausible?)
- output response: forward guidance puzzle, model too forward looking

HANK solutions?

Major goal of early HANK papers: solve these two issues!

HANK solutions?

Major goal of early HANK papers: solve these two issues!

- Auclert (2019), Kaplan et al. (2018): indirect channels become important for monetary transmission (e.g. redistribution or labor income)
- McKay et al. (2016): borrowing constraints make consumption less forward looking ⇒ get something like

$$c_{t} = \delta c_{t+1} - \sigma^{-1} (i_{t} - \pi_{t+1})$$
 with $\delta < 1$ (DEE)

This would dampen forward guidance!

HANK solutions?

Major goal of early HANK papers: solve these two issues!

- Auclert (2019), Kaplan et al. (2018): indirect channels become important for monetary transmission (e.g. redistribution or labor income)
- McKay et al. (2016): borrowing constraints make consumption less forward looking ⇒ get something like

$$c_{t} = \delta c_{t+1} - \sigma^{-1} (i_{t} - \pi_{t+1})$$
 with $\delta < 1$ (DEE)

This would dampen forward guidance!

Next: What HANK actually does!

6

Monetary policy in the canonical HANK model

Setting up the model

- Take canonical HANK model, but abstract from fiscal policy
 - $T = \tau = G = B = 0$
 - but allow agents to borrow from each other: $\underline{a} < o$ (as in Huggett model)
 - later bring back government to study monetary-fiscal interactions
- Real rate rule: monetary policy sets $r_t^{ante} = i_t \pi_{t+1}$ directly

7

Setting up the model

- Take canonical HANK model, but abstract from fiscal policy
 - $T = \tau = G = B = 0$
 - but allow agents to borrow from each other: $\underline{a} < o$ (as in Huggett model)
 - later bring back government to study monetary-fiscal interactions
- Real rate rule: monetary policy sets $r_t^{ante} = i_t \pi_{t+1}$ directly
- Ask two questions:
 - 1. Output response relative to RA? (Magnitude? Any "discounting"?)
 - 2. Transmission channels relative to RA?

Setting up the model

- Take canonical HANK model, but abstract from fiscal policy
 - $T = \tau = G = B = 0$
 - but allow agents to borrow from each other: $\underline{a} < o$ (as in Huggett model)
 - later bring back government to study monetary-fiscal interactions
- Real rate rule: monetary policy sets $r_t^{ante} = i_t \pi_{t+1}$ directly
- Ask two questions:
 - 1. Output response relative to RA? (Magnitude? Any "discounting"?)
 - 2. Transmission channels relative to RA?

We'll start with 1.

Back to our equilibrium conditions

Under these assumptions, the canonical HANK model can just be written as:

$$\max_{c_{it}} \mathbb{E}_{o} \sum_{t=o}^{\infty} \beta^{t} \left(u(c_{it}) - v(N_{t}) \right)$$

$$c_{it} + a_{it} \leq (1 + r_{t-1}^{ante}) a_{it-1} + e_{it} Y_{t}$$

$$a_{it} \geq \underline{a}$$

with

$$C_t \equiv \int c_{it} di = Y_t = N_t$$
 $A_t \equiv \int a_{it} di = 0$

Back to our equilibrium conditions

Under these assumptions, the canonical HANK model can just be written as:

$$\max_{c_{it}} \mathbb{E}_{o} \sum_{t=o}^{\infty} \beta^{t} \left(u(c_{it}) - v(N_{t}) \right)$$

$$c_{it} + a_{it} \leq (1 + r_{t-1}^{ante}) a_{it-1} + e_{it} Y_{t}$$

$$a_{it} \geq \underline{a}$$

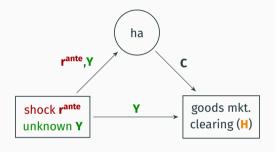

with

$$C_t \equiv \int c_{it} di = Y_t = N_t$$
 $A_t \equiv \int a_{it} di = 0$

That's it!

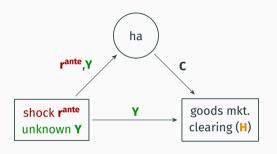

DAG of this model

Let's visualize this as a DAG:

DAG of this model

Let's visualize this as a DAG:

Here again, simple fixed point:

$$C_t\left(\left\{r_s^{ante}, Y_s\right\}\right) = Y_t$$

9

Ex-ante vs ex-post r

• In practice, we usually write HetBlocks with "ex-post r" convention, i.e. here:

$$\max_{c_{it}} \mathbb{E}_{o} \sum_{t=o}^{\infty} \beta^{t} \left(u(c_{it}) - v(N_{t}) \right)$$

$$c_{it} + a_{it} \leq (1 + r_{t})a_{it-1} + s_{it}Y_{t}$$

$$a_{it} \geq \underline{a}$$

• This is more general: allows us to handle valuation effects (see next lecture)

Ex-ante vs ex-post *r*

• In practice, we usually write HetBlocks with "ex-post r" convention, i.e. here:

$$\max_{c_{it}} \mathbb{E}_{o} \sum_{t=o}^{\infty} \beta^{t} \left(u(c_{it}) - v(N_{t}) \right)$$

$$c_{it} + a_{it} \leq (1 + r_{t}) a_{it-1} + s_{it} Y_{t}$$

$$a_{it} \geq \underline{a}$$

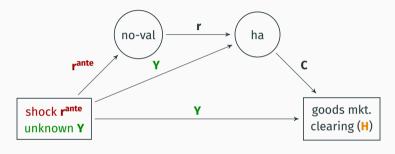

- This is more general: allows us to handle valuation effects (see next lecture)
- Here there are no valuation effects, so we just have

$$r_t = r_{t-1}^{ante} \quad t \ge 1$$
 $r_0 = r_{ss}$

This adds one "no valuation" block to the DAG

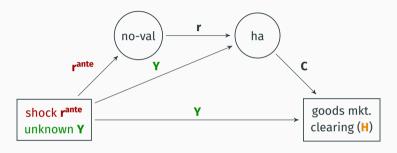

DAG including the valuation block

Our new DAG is:

DAG including the valuation block

Our new DAG is:

If we are fancy, we could use CombinedBlock in SSJ to do the convolution

$$\tilde{\mathcal{C}}_{t}\left(\left\{r_{s}^{ante},Y_{s}\right\}\right)\equiv\mathcal{C}_{t}\left(\left\{r_{j}\left(r_{s}^{ante}\right),Y_{s}\right\}\right)$$

So that we are back to our simple fixed point:

$$\mathcal{\tilde{C}}_{t}\left(\left\{ r_{s}^{ante},\mathsf{Y}_{s}
ight\}
ight) =\mathsf{Y}_{t}$$

- As in fiscal lecture, let's linearize this sequence space equation
- Define $d\mathbf{r}^{ante} \equiv (dr_0^{ante}, dr_1^{ante}, \ldots)$, and let $d\mathbf{Y} = (dY_0, dY_1, \ldots)$ as before. Define Jacobian $\mathbf{M}^r \equiv (\partial \tilde{\mathcal{C}}_t/\partial r_s^{ante})_{t,s}$ capturing direct effect of r on C.

- As in fiscal lecture, let's linearize this sequence space equation
- Define $d\mathbf{r}^{ante} \equiv (dr_0^{ante}, dr_1^{ante}, \ldots)$, and let $d\mathbf{Y} = (dY_0, dY_1, \ldots)$ as before. Define Jacobian $\mathbf{M}^r \equiv (\partial \tilde{\mathcal{C}}_t/\partial r_s^{ante})_{t.s}$ capturing direct effect of r on C. Then:

$$d\mathbf{Y} = \mathbf{M}^r d\mathbf{r}^{ante} + \mathbf{M} d\mathbf{Y}$$

- As in fiscal lecture, let's linearize this sequence space equation
- Define $d\mathbf{r}^{ante} \equiv (dr_0^{ante}, dr_1^{ante}, \ldots)$, and let $d\mathbf{Y} = (dY_0, dY_1, \ldots)$ as before. Define Jacobian $\mathbf{M}^r \equiv \left(\partial \tilde{\mathcal{C}}_t/\partial r_s^{ante}\right)_{t,s}$ capturing direct effect of r on C. Then:

$$d\mathbf{Y} = \mathbf{M}^r d\mathbf{r}^{ante} + \mathbf{M} d\mathbf{Y}$$

 Almost like the IKC, except that partial eqbm demand shock is no longer coming from fiscal policy, dG — MdT, but instead from monetary policy!

- As in fiscal lecture, let's linearize this sequence space equation
- Define $d\mathbf{r}^{ante} \equiv (dr_0^{ante}, dr_1^{ante}, \ldots)$, and let $d\mathbf{Y} = (dY_0, dY_1, \ldots)$ as before. Define Jacobian $\mathbf{M}^r \equiv \left(\partial \tilde{\mathcal{C}}_t/\partial r_s^{ante}\right)_{t,s}$ capturing direct effect of r on C. Then:

$$d\mathbf{Y} = \mathbf{M}^r d\mathbf{r}^{ante} + \mathbf{M} d\mathbf{Y}$$

- Almost like the IKC, except that partial eqbm demand shock is no longer coming from fiscal policy, dG — MdT, but instead from monetary policy!
- Just as with fiscal, the PE demand shock has zero NPV (Why?)

- As in fiscal lecture, let's linearize this sequence space equation
- Define $d\mathbf{r}^{ante} \equiv (dr_0^{ante}, dr_1^{ante}, \ldots)$, and let $d\mathbf{Y} = (dY_0, dY_1, \ldots)$ as before. Define Jacobian $\mathbf{M}^r \equiv (\partial \tilde{\mathcal{C}}_t/\partial r_s^{ante})_{t,s}$ capturing direct effect of r on C. Then:

$$d\mathbf{Y} = \mathbf{M}^r d\mathbf{r}^{ante} + \mathbf{M} d\mathbf{Y}$$

- Almost like the IKC, except that partial eqbm demand shock is no longer coming from fiscal policy, dG — MdT, but instead from monetary policy!
- Just as with fiscal, the PE demand shock has zero NPV (Why?)
- General solution uses same linear mapping \mathcal{M} (recall " $(I M)^{-1}$ ")

$$d\mathbf{Y} = \mathcal{M}\mathbf{M}^r d\mathbf{r}^{ante}$$

- As in fiscal lecture, let's linearize this sequence space equation
- Define $d\mathbf{r}^{ante} \equiv (dr_{o}^{ante}, dr_{1}^{ante}, \ldots)$, and let $d\mathbf{Y} = (dY_{o}, dY_{1}, \ldots)$ as before. Define Jacobian $\mathbf{M}^{r} \equiv (\partial \tilde{\mathcal{C}}_{t}/\partial r_{s}^{ante})_{t,s}$ capturing direct effect of r on C. Then:

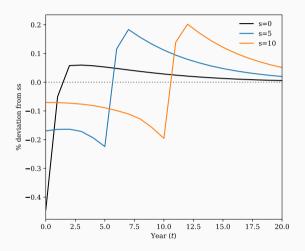

$$d\mathbf{Y} = \mathbf{M}^r d\mathbf{r}^{ante} + \mathbf{M} d\mathbf{Y}$$

- Almost like the IKC, except that partial eqbm demand shock is no longer coming from fiscal policy, dG — MdT, but instead from monetary policy!
- Just as with fiscal, the PE demand shock has zero NPV (Why?)
- General solution uses same linear mapping \mathcal{M} (recall " $(I M)^{-1}$ ")

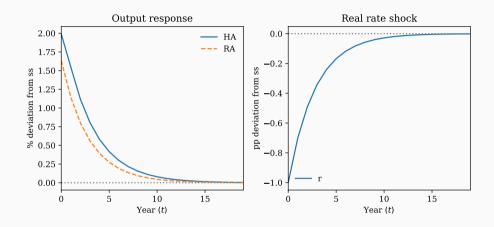

$$d\mathbf{Y} = \mathcal{M}\mathbf{M}^{r}d\mathbf{r}^{ante}$$

Next: Let's visualize \mathbf{M}^r ; then the solution $d\mathbf{Y}$ for an AR(1) shock to $d\mathbf{r}^{ante}$

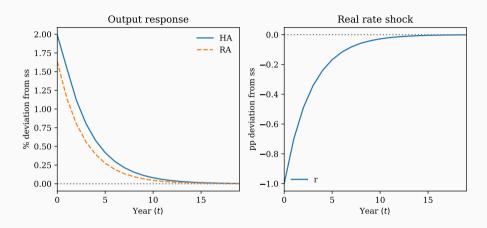

Columns of Jacobian \mathbf{M}^r

Monetary policy shock in HA (AR(1) with $\rho = 0.7$)

Monetary policy shock in HA (AR(1) with $\rho = 0.7$)

• HA > RA! Interesting! But why?

Benchmark result with zero liquidity

ullet One way to make progress is to simplify the model \Rightarrow ZL model: $\underline{a} \rightarrow$ O

Benchmark result with zero liquidity

- One way to make progress is to simplify the model \Rightarrow ZL model: $\underline{a} \rightarrow$ O
- Recall that in ss only Euler equation of agents in high income state \bar{s} holds

$$(\mathbf{Y}_{t}\overline{\mathbf{S}})^{-\sigma} = \beta \left(\mathbf{1} + r_{t}^{ante}\right) \mathbb{E}_{t} \left[\left(\mathbf{Y}_{t+1}\mathbf{S}'\right)^{-\sigma} | \overline{\mathbf{S}} \right]$$

Benchmark result with zero liquidity

- One way to make progress is to simplify the model \Rightarrow ZL model: $\underline{a} \rightarrow$ O
- Recall that in ss only Euler equation of agents in high income state \bar{s} holds

$$(\mathbf{Y}_{t}\overline{\mathbf{S}})^{-\sigma} = \beta \left(\mathbf{1} + r_{t}^{ante}\right) \mathbb{E}_{t} \left[\left(\mathbf{Y}_{t+1}\mathbf{S}'\right)^{-\sigma} | \overline{\mathbf{S}} \right]$$

• Define $\overline{
ho}\equiv \mathbb{E}\left[\left(s'/\overline{s}\right)^{-\sigma}|\overline{s}\right]$. Then, we always have

$$Y_{t}^{-\sigma} = \beta \overline{\rho} \left(1 + r_{t}^{ante} \right) Y_{t+1}^{-\sigma} \quad \Rightarrow \quad y_{t} = y_{t+1} - \sigma^{-1} \left(r_{t}^{ante} - \log \left(\beta \overline{\rho} \right) \right)$$

Benchmark result with zero liquidity

- One way to make progress is to simplify the model \Rightarrow ZL model: $\underline{a} \rightarrow$ O
- Recall that in ss only Euler equation of agents in high income state \bar{s} holds

$$(\mathbf{Y}_{t}\overline{\mathbf{S}})^{-\sigma} = \beta \left(\mathbf{1} + \mathbf{r}_{t}^{ante}\right) \mathbb{E}_{t} \left[\left(\mathbf{Y}_{t+1}\mathbf{S}'\right)^{-\sigma} | \overline{\mathbf{S}} \right]$$

ullet Define $\overline{
ho}\equiv \mathbb{E}\left[\left(s'/\overline{s}
ight)^{-\sigma}|\overline{s}
ight]$. Then, we always have

$$Y_{t}^{-\sigma} = \beta \overline{\rho} \left(1 + r_{t}^{ante} \right) Y_{t+1}^{-\sigma} \quad \Rightarrow \quad y_{t} = y_{t+1} - \sigma^{-1} \left(r_{t}^{ante} - \log \left(\beta \overline{\rho} \right) \right)$$

- This is like our representative agent Euler equation!
 - HA = RA with effective discount factor $\beta \overline{\rho}$
 - ightarrow Werning (2015)'s **neutrality result** for zero liquidity and acyclical income risk

Benchmark result with zero liquidity

- ullet One way to make progress is to simplify the model \Rightarrow ZL model: $\underline{a} \rightarrow$ O
- Recall that in ss only Euler equation of agents in high income state \bar{s} holds

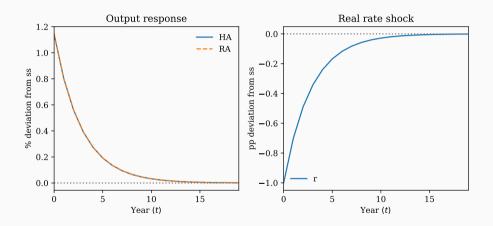

$$(Y_{t}\overline{s})^{-\sigma} = \beta \left(1 + r_{t}^{ante}\right) \mathbb{E}_{t} \left[\left(Y_{t+1}s'\right)^{-\sigma} | \overline{s}
ight]$$

• Define $\overline{
ho}\equiv \mathbb{E}\left[\left(s'/\overline{s}\right)^{-\sigma}|\overline{s}\right]$. Then, we always have

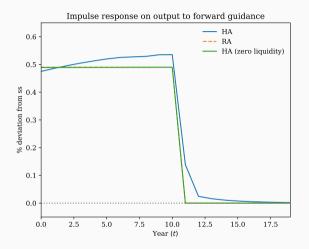

$$Y_{t}^{-\sigma} = \beta \overline{\rho} \left(1 + r_{t}^{ante} \right) Y_{t+1}^{-\sigma} \quad \Rightarrow \quad y_{t} = y_{t+1} - \sigma^{-1} \left(r_{t}^{ante} - \log \left(\beta \overline{\rho} \right) \right)$$

- This is like our representative agent Euler equation!
 - HA = RA with effective discount factor $\beta \overline{\rho}$
 - \rightarrow Werning (2015)'s **neutrality result** for zero liquidity and acyclical income risk
- In particular: No discounting in log-linearized Euler equation!

Neutrality for monetary policy in the ZL limit

Neutrality also implies the forward guidance puzzle is not solved by HA

Summary: Output response of monetary policy in HA

- No robust result that $HA \neq RA$!
 - in fact, with zero liquidity, we showed that HA = RA!
 - forward guidance can be equally powerful

Summary: Output response of monetary policy in HA

- No robust result that $HA \neq RA$!
 - in fact, with zero liquidity, we showed that HA = RA!
 - forward guidance can be equally powerful
- But how can that be, given that HA breaks the Euler equation?
- Next: study transmission channels

monetary policy

• To see what's going on, let's go back to our IKC-like equation:

$$d\mathbf{Y} = d\mathbf{C} = \underbrace{\mathbf{M}^r \cdot d\mathbf{r}^{ante}}_{\text{Direct effect}} + \underbrace{\mathbf{M} \cdot d\mathbf{Y}}_{\text{Indirect effect}}$$

• To see what's going on, let's go back to our IKC-like equation:

$$d\mathbf{Y} = d\mathbf{C} = \underbrace{\mathbf{M}^r \cdot d\mathbf{r}^{ante}}_{\text{Direct effect}} \downarrow + \underbrace{\mathbf{M} \cdot d\mathbf{Y}}_{\text{Indirect effect}} \uparrow$$

Two competing effects of market incompleteness! direct ↓, indirect ↑

[Kaplan et al. (2018) showed this in their two-account HA model]

• To see what's going on, let's go back to our IKC-like equation:

$$d\mathbf{Y} = d\mathbf{C} = \underbrace{\mathbf{M}^r \cdot d\mathbf{r}^{ante}}_{\text{Direct effect}} \downarrow + \underbrace{\mathbf{M} \cdot d\mathbf{Y}}_{\text{Indirect effect}} \uparrow$$

- Two competing effects of market incompleteness! direct ↓, indirect ↑
 [Kaplan et al. (2018) showed this in their two-account HA model]
- Why? High MPCs make C more sensitive to Y but also less sensitive to rante!

• To see what's going on, let's go back to our IKC-like equation:

$$d\mathbf{Y} = d\mathbf{C} = \underbrace{\mathbf{M}^r \cdot d\mathbf{r}^{ante}}_{\text{Direct effect}} \downarrow + \underbrace{\mathbf{M} \cdot d\mathbf{Y}}_{\text{Indirect effect}} \uparrow$$

- Two competing effects of market incompleteness! direct ↓, indirect ↑
 [Kaplan et al. (2018) showed this in their two-account HA model]
- Why? High MPCs make C more sensitive to Y but also less sensitive to rante!
 - cf Auclert (2019): substitution effect of dr^{ante} scales with $-\sigma^{-1}(1-MPC)$

• To see what's going on, let's go back to our IKC-like equation:

$$d\mathbf{Y} = d\mathbf{C} = \underbrace{\mathbf{M}^r \cdot d\mathbf{r}^{ante}}_{\text{Direct effect}} \downarrow + \underbrace{\mathbf{M} \cdot d\mathbf{Y}}_{\text{Indirect effect}} \uparrow$$

Two competing effects of market incompleteness! direct ↓, indirect ↑

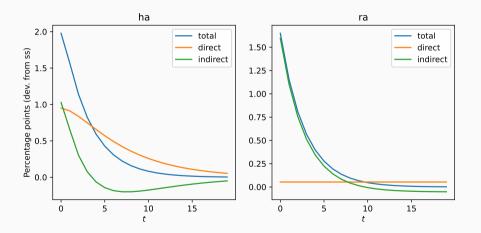

[Kaplan et al. (2018) showed this in their two-account HA model]

- Why? High MPCs make C more sensitive to Y but also less sensitive to rante!
 - cf Auclert (2019): substitution effect of dr^{ante} scales with $-\sigma^{-1}(1-MPC)$
 - In ZL model, can actually prove that $\mathbf{M}^{r} = -\sigma^{-1}(\mathbf{I} \mathbf{M})\mathbf{U}$ so

$$d\mathbf{C} = -\sigma^{-1}(\mathbf{I} - \mathbf{M})\mathbf{U} \cdot d\mathbf{r}^{ante} + \mathbf{M} \cdot d\mathbf{Y}$$

Decomposition into direct and indirect effects

• Let's implement $d\mathbf{C} = \mathbf{M}^r d\mathbf{r}^{ante} + \mathbf{M} \cdot d\mathbf{Y}$ in our canonical HA model:

Cyclical income risk

Introducing cyclical income risk

 A simple way to introduce cyclical income risk by adopting different labor allocation rule. Auclert and Rognlie (2018) propose

$$n_{it} = Y_t \frac{(e_{it})^{\zeta \log Y_t}}{\mathbb{E}\left[e_i^{1+\zeta \log Y_t}\right]} \equiv Y_t \Gamma\left(e_{it}, Y_t\right)$$

Introducing cyclical income risk

• A simple way to introduce cyclical income risk by adopting different labor allocation rule. Auclert and Rognlie (2018) propose

$$n_{it} = Y_{t} \frac{(e_{it})^{\zeta \log Y_{t}}}{\mathbb{E}\left[e_{i}^{1+\zeta \log Y_{t}}\right]} \equiv Y_{t} \Gamma\left(e_{it}, Y_{t}\right)$$

• Distribution of income $y_{it} \equiv e_{it} n_{it}$ now reacts to monetary policy

$$sd (\log y_{it}) = (1 + \zeta \log Y_t) sd (\log e_i)$$

- $\zeta >$ 0: procyclical inequality and income risk
- ζ < 0: countercyclical inequality and income risk
- $\zeta = o$ is benchmark from above (acyclical inequality & risk)

Introducing cyclical income risk

 A simple way to introduce cyclical income risk by adopting different labor allocation rule. Auclert and Rognlie (2018) propose

$$n_{it} = Y_t \frac{(e_{it})^{\zeta \log Y_t}}{\mathbb{E}\left[e_i^{1+\zeta \log Y_t}\right]} \equiv Y_t \Gamma\left(e_{it}, Y_t\right)$$

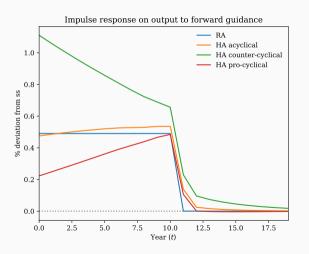

• Distribution of income $y_{it} \equiv e_{it} n_{it}$ now reacts to monetary policy

$$sd (\log y_{it}) = (1 + \zeta \log Y_t) sd (\log e_i)$$

- $\zeta > 0$: procyclical inequality and income risk
- ζ < 0: countercyclical inequality and income risk
- $\zeta = o$ is benchmark from above (acyclical inequality & risk)
- Matters because:
 - current shocks redistribute between different MPCs ("cyclical inequality")
 - future shocks change income risk ("cyclical risk")

Countercyclical income risk makes the forward guidance puzzle worse!

• Consider a r_T shock with three calibrations for ζ in HA model

What's going on? In ZL limit, we get an **exact** discounted Euler equation

$$y_t = \underline{\delta} \cdot \mathbb{E}_t \left[y_{t+1} \right] - \sigma^{-1} \cdot \operatorname{const} \cdot \left(r_t^{ante} - \log \left(\beta \overline{\rho} \right) \right)$$

where δ depends on cyclicality of income risk ζ .

What's going on? In ZL limit, we get an **exact** discounted Euler equation

$$y_t = \underline{\delta} \cdot \mathbb{E}_t \left[y_{t+1} \right] - \sigma^{-1} \cdot \mathsf{const} \cdot \left(r_t^{ante} - \log \left(\beta \overline{\rho} \right) \right)$$

where δ depends on cyclicality of income risk ζ .

1. Dynamic discounting (δ < 1) $\Leftrightarrow \zeta$ > 0 procyclical risk (less common)

What's going on? In ZL limit, we get an **exact** discounted Euler equation

$$y_t = \underline{\delta} \cdot \mathbb{E}_t \left[y_{t+1} \right] - \sigma^{-1} \cdot \mathsf{const} \cdot \left(r_t^{ante} - \log \left(\beta \overline{\rho} \right) \right)$$

where δ depends on cyclicality of income risk ζ .

- 1. Dynamic discounting (δ < 1) $\Leftrightarrow \zeta$ > 0 procyclical risk (less common)
- 2. Dynamic amplification ($\delta > 1$) $\Leftrightarrow \zeta < 0$ countercyclical risk (more common)
 - microfound w/ u: Ravn and Sterk (2017), den Haan et al. (2018), Challe (2020)
 - lots of evidence: Storesletten et al. (2004), Guvenen et al. (2014)

What's going on? In ZL limit, we get an **exact** discounted Euler equation

$$y_t = \underline{\delta} \cdot \mathbb{E}_t \left[y_{t+1} \right] - \sigma^{-1} \cdot \operatorname{const} \cdot \left(r_t^{ante} - \log \left(\beta \overline{\rho} \right) \right)$$

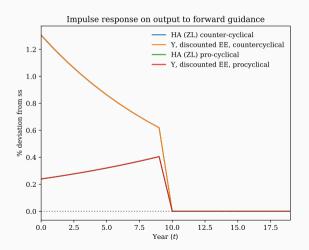

where δ depends on cyclicality of income risk ζ .

- 1. Dynamic discounting (δ < 1) $\Leftrightarrow \zeta$ > 0 procyclical risk (less common)
- 2. Dynamic amplification ($\delta > 1$) $\Leftrightarrow \zeta < 0$ countercyclical risk (more common)
 - microfound w/ u: Ravn and Sterk (2017), den Haan et al. (2018), Challe (2020)
 - lots of evidence: Storesletten et al. (2004), Guvenen et al. (2014)
- 3. Dynamic neutrality ($\delta=1$) $\Leftrightarrow \zeta=0$ acyclical risk, as in Werning

Why? Precautionary savings. Think about logic of discounted Euler equation.

Forward guidance in the ZL model

• In the empirically plausible case, the fwd guidance puzzle is **aggravated**! Bilbiie (2021), Acharya and Dogra (2020)

• In richer models income of agents typically involves multiple components,

$$y_{it} = \frac{W_t}{P_t} n_{it} s_{it} - \underbrace{\tau_{it}}_{\text{taxes}} + \underbrace{T_{it}}_{\text{transfers}}$$

These also matter for cyclicality of income risk

• In richer models income of agents typically involves multiple components,

$$y_{it} = \frac{W_t}{P_t} n_{it} s_{it} - \underbrace{\tau_{it}}_{\text{taxes}} + \underbrace{T_{it}}_{\text{transfers}}$$

- These also matter for cyclicality of income risk
- For example, suppose taxes are set to keep balanced budget, $\tau_t \equiv \int \tau_{it} di = r_t^{ante} B$ and transfers T_t are div's from firms with sticky prices

• In richer models income of agents typically involves multiple components,

$$y_{it} = \frac{W_t}{P_t} n_{it} s_{it} - \underbrace{\tau_{it}}_{\text{taxes}} + \underbrace{T_{it}}_{\text{transfers}}$$

- These also matter for cyclicality of income risk
- For example, suppose taxes are set to keep balanced budget, $\tau_t \equiv \int \tau_{it} di = r_t^{ante} B$ and transfers T_t are div's from firms with sticky prices \Rightarrow both τ_t and T_t fall after expansionary r_t^{ante} (why?)

In richer models income of agents typically involves multiple components,

$$y_{it} = \frac{W_t}{P_t} n_{it} s_{it} - \underbrace{\tau_{it}}_{\text{taxes}} + \underbrace{T_{it}}_{\text{transfers}}$$

- These also matter for cyclicality of income risk
- For example, suppose taxes are set to keep balanced budget, $\tau_t \equiv \int \tau_{it} di = r_t^{ante} B$ and transfers T_t are div's from firms with sticky prices \Rightarrow both τ_t and T_t fall after expansionary r_t^{ante} (why?)
- If τ_t allocated to highest income state and T_t to all \Rightarrow procyclical risk!

• In richer models income of agents typically involves multiple components,

$$y_{it} = \frac{W_t}{P_t} n_{it} s_{it} - \underbrace{\tau_{it}}_{\text{taxes}} + \underbrace{T_{it}}_{\text{transfers}}$$

- These also matter for cyclicality of income risk
- For example, suppose taxes are set to keep balanced budget, $\tau_t \equiv \int \tau_{it} di = r_t^{ante} B$ and transfers T_t are div's from firms with sticky prices \Rightarrow both τ_t and T_t fall after expansionary r_t^{ante} (why?)
- If τ_t allocated to highest income state and T_t to all \Rightarrow procyclical risk!
- These are the assumptions in McKay et al. (2016).
 - Reason why that paper "solves" the forward guidance puzzle!

Summary: Cyclical income risk

- Cyclical income risk matters
- ullet Procyclical income risk \Rightarrow weakens monetary policy + fwd guidance
 - ... but not empirically supported
- Countercyclical income risk is empirically more plausible
 - ... but aggravates forward guidance puzzle!

Takeaway

Takeaway: Monetary policy with heterogeneous agents

- 1. HA model does not imply robustly different output response
 - Except to the extent that income risk is pro/countercyclical
- 2. But it does change transmission: indirect effects are more important!

Takeaway: Monetary policy with heterogeneous agents

- 1. HA model does not imply robustly different output response
 - Except to the extent that income risk is pro/countercyclical
- 2. But it does change transmission: indirect effects are more important!
 - This is the main result in KMV. Why do we care about that per se?

Takeaway: Monetary policy with heterogeneous agents

- 1. HA model does not imply robustly different output response
 - Except to the extent that income risk is pro/countercyclical
- 2. But it does change transmission: indirect effects are more important!
 - This is the main result in KMV. Why do we care about that per se?
 - KMV: labor & financial market institutions matter more than we thought
 - We'll see other reasons for why we should care in the next lecture

• Take ZL model with cyclical income risk. Euler for \$\overline{s}\$:

$$(Y_{t}\Gamma\left(\overline{s},Y_{t}\right))^{-\sigma}=\beta\left(1+r_{t}^{ante}\right)\mathbb{E}_{t}\left[\left(Y_{t+1}\Gamma\left(s',Y_{t+1}\right)\right)^{-\sigma}|\overline{s}\right]$$

• Log-linearize around steady state ⇒

$$y_t = \frac{\delta \mathbb{E}_t \left[y_{t+1} \right] - \sigma^{-1} \gamma(\overline{s})^{-1} \left(r_t^{ante} - \log \left(\beta \overline{\rho} \right) \right)$$

where, if $\gamma(s) \equiv 1 + \frac{\Gamma_Y Y}{\Gamma}$ is the elasticity of income wrt Y for agent in s:

$$\delta \equiv \overline{\rho}^{-1} \mathbb{E}\left[(s/\overline{s})^{-\sigma} \frac{\gamma(s)}{\gamma(\overline{s})} | \overline{s} \right] = \sum \omega(s) \frac{\gamma(s)}{\gamma(\overline{s})} \quad \text{where } \sum_{s} \omega(s) = 1$$

- What matters is cyclicality of $y(\bar{s})$ relative to other income states
- Example with two states: $\delta = 1 \omega + \omega \frac{\gamma_L}{\gamma_H}$ with $\omega \in (0, 1)$
